

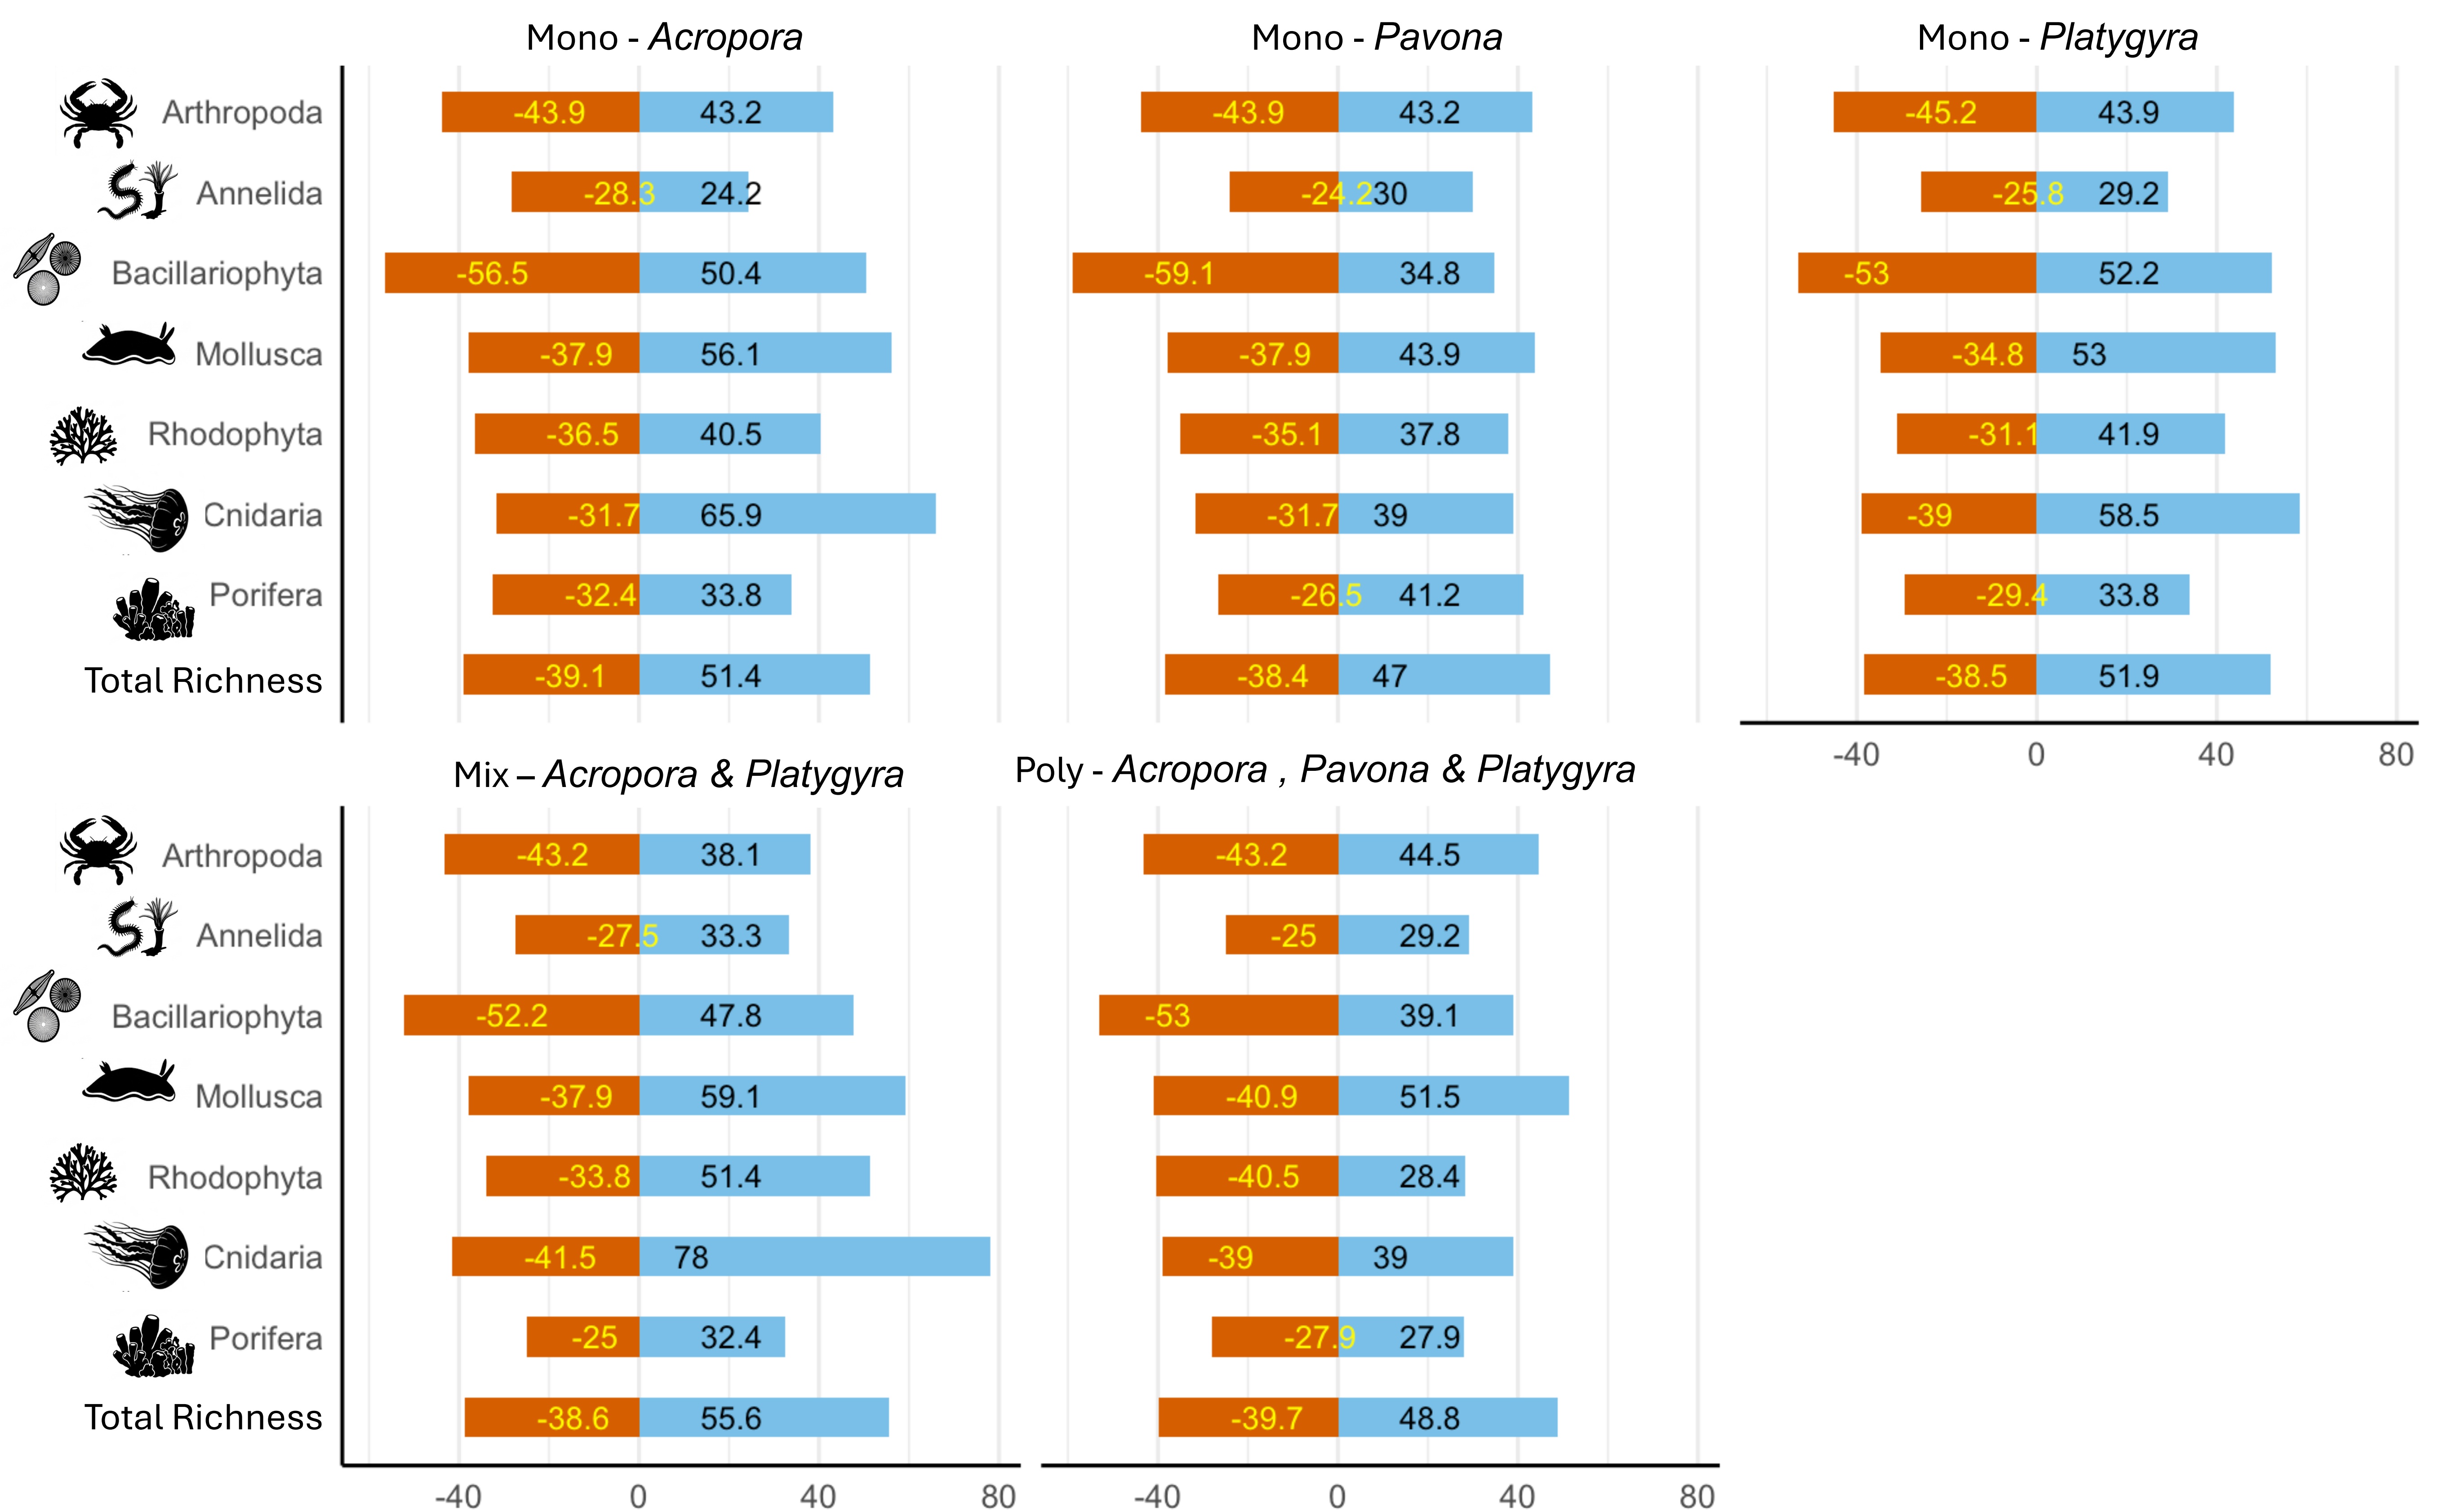

Figure 4: Percentage gains (blue) and losses (red) in phylum-level OTU richness for each active restoration treatment relative to the control. Values represent the percent difference in pooled OTU richness per phylum between each coral-seeded treatment and the unseeded control, calculated as $[(\text{treatment richness} - \text{control richness}) / \text{control richness}] \times 100$. Phyla shown include Arthropoda, Annelida, Bacillariophyta (diatoms), Mollusca, Rhodophyta (red algae), Cnidaria, and Porifera. The "Total Richness" row at the bottom of each panel shows the percentage change in total OTU richness across all OTU combined. Positive values (blue) represent taxa present in the coral-seeded treatment but absent in the control (gain); negative values (red) represent taxa absent in the seeded treatment but present in the control (loss). Communities in the control treatment consistently exhibited lower pooled OTU richness than any coral-seeded treatment.
